Algebraic Positional Encodings

Konstantinos Kogkalidis Jean-Philippe Bernardy Vikas Garg

TL;DR

"syntax is an algebra, semantics is an algebra, and meaning is a homomorphism between them"

Montague's theory of meaning

We argue that:

- understanding and explicating the formation rules and rewrite properties of **positions** over different **ambient structures** (*syntax*)
- and finding appropriate structure-preserving **interpretations** (*meaning*) is the only way to structure-faithful **positional encodings** (semantics).

We call these Algebraic Positional Encodings (APE). APE readily apply to:

- sequences
- trees
- grids

We show that **sequential APE theoretically subsume RoPE**. Beyond sequences, APE are a **theoretically disciplined and highly general extension of RoPE across multiple dimensions** (both metaphorical and literal).

Sequences

Let \mathbb{P} be a *path* (*i.e.*, a relative offset) between two points in a sequence.

P admits a simple inductive definition:

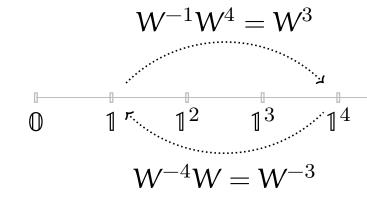

$$\mathbb{P} := \mathbb{1}$$
 # take a step to the right
 $|\mathbb{P} + \mathbb{P}|$ # join two paths together
 $|\mathbb{P}^{-1}|$ # flip a path around

where + associative and commutative with $0 := 1 + 1^{-1}$ as its neutral element.

Remark 1. The signature coincides with that of the integers, $\mathbb{P} \equiv \mathbb{Z}$.

Remark 2. The signature corresponds to an infinite cyclic group, $\mathbb{P} \equiv \langle \mathbb{1} \rangle$. **Remark 3.** The signature admits a representation in $O(\mathfrak{n})$. Consider the interpretation $[]:\langle \mathbb{1} \rangle \to \langle W \rangle$, such that:

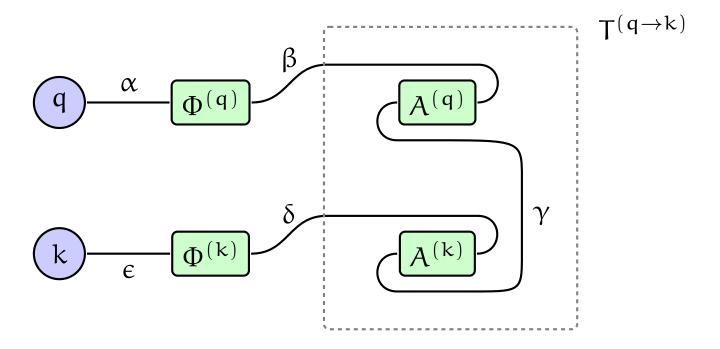

Remark 4. $A \to B = (A \to 0) + (0 \to B)$. Visually:

Remark 5. This setup offers an inductive parameterization of sequential PE using just one trainable primitive (a single matrix).

How-To

Simply substitute dot-product for the tensor contraction:

where:

- $q, k \in \mathbb{R}^n$
- $\Phi^{(q,k)} \in \mathbb{R}^{n \times n}$
- $A^{(q,k)} \in O(n)$ the representations of the positions of q and k

Note: $T^{(q \to k)} = A^{(q)} A^{(k)}$ the **path** representation from q to k

In the sequential setup RoPE \equiv APE, except with a fixed W. Why?

Hint: $W = QRQ^{\top}$ (where $Q \in O(n)$ and R a block-diagonal rotation).

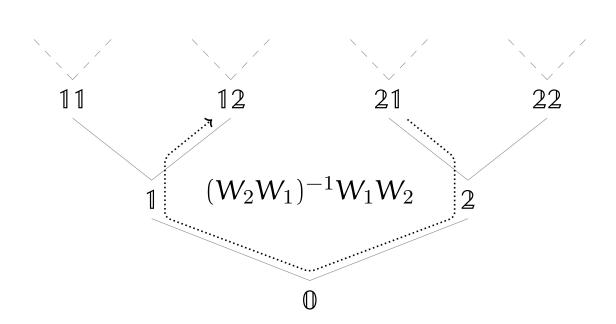

Trees

Extend the definition of P with **options**, to arrive at a definition of paths \mathbb{P}_{κ} over κ-ary branching trees:

$$\begin{array}{ll} \mathbb{P}_{\kappa} := 1 & \text{\# take the first branch} \\ | 2 & \text{\# take the second branch} \\ | \dots & \\ | \kappa & \text{\# take the κ-th branch} \\ | \mathbb{P} + \mathbb{P} & \text{\# join two paths together} \\ | \mathbb{P}^{-1} & \text{\# flip a path around} \end{array}$$

Remark 5. This is now a generic group with κ generators. Remark 6. Unlike sequences, the structure is not commutative.

Remark 7. All else remains the same – just extend the interpretation to: $\langle 1, 2, \dots, \kappa \rangle \rightarrow \langle W_1, W_2, \dots, W_{\kappa} \rangle$. Visually:

Grids

Rather than add options, we can glue two (or more) sequences together by means of the **group direct sum**, \oplus . Consider the composite group $\mathbb{P}^2 := \mathbb{P} \oplus \mathbb{P}$, with the group operation and inversion defined as:

$$(x,y) + (z,w) = (x+z,y+w)$$

 $(x,y)^{-1} = (x^{-1},y^{-1})$

Remark 8. The structure is commutative once more.

Remark 9. Elements of \mathbb{P}^2 are still to be interpreted as (orthogonal) matrices, except now block-structured, by virtue of the matrix direct sum:

$$\lceil \mathfrak{p} \oplus \mathfrak{q} \rceil \mapsto \lceil \mathfrak{p} \rceil \oplus \lceil \mathfrak{q} \rceil = \begin{bmatrix} \lceil \mathfrak{p} \rceil & 0 \\ 0 & \lceil \mathfrak{q} \rceil \end{bmatrix}$$

Visually:

Remark 10. The same interpretation strategy can be applied to construct any other composition of established structures and their representations.

Results

We get really good results in many different setups (sequence transduction/tree manipulation/image recognition).

Details omitted for suspense (and space economy).
